THE INFLUENCE OF CHAMBER DIAMETER ON THE MUZZLE VELOCITY OF A GUN WITH AN EFFECTIVELY INFINITE LENGTH CHAMBER

Prepared by:

Arnold E. Seigel

ABSTRACT: This report is a theoretical study of the influence of chambrage (the ratio of chamber diameter to bore diameter) on the mussle velocity of a gun. The analysis is applied to a chambered gun in which all the propellant is burned before the projectile noves; the cylindrical chamber is assumed to be of sufficient length so that the breech has no effect on the projectile motion. Thus, the influence of chambrage is present, while the effects of the propellant burning during firing and of the breech are not. The propellant gas is treated as an ideal gas. The change of state of the gas in passing through the section of reduction in diameter is obtained by applying the steady state isentropic equations of continuity and energy. Unsteady isentropic flow is assumed in all other parts of the gun.

NAVORD Remort 3635

26 January 1754

This report presents further results of a theoretical study of the effect of gum chambrage (the ratio of propellant chamber diameter to barrol bore dismeter) on the mussle velocity of gums. It considers the effect of finite chambrage and is a sequel to NAVORD Report 2691, which treats the special case of infinite chambrage. This study was made in order to augment our interior ballistics knowledge with the ultimate aim of obtaining high gum velocities. The work was carried out under project No. FR-33-(54).

THE INFLUENCE OF CHAMBER DIAMETER ON THE MUZZLE VELOCITY OF A GUN WITH AN EFFECTIVELY INFINITE LENGTH CHAMBER

I. INTRODUCTION

- 1. The influence of chambrage, the ratio of the propellant chamber diameter to the barrel bore diameter, has been theoretically examined in reference (a) for the special case known as "optimum chambrage". This condition of chambrage equal to infinity yields the maximum possible projectile velocity for given gun and propellant parameters." (In most instances the optimum chambrage conditions can be approached by either a large, well-shaped chamber in which the propellant has been initially all burned or by a propellant burning at the proper rate in a smaller chamber (see reference (a).) It is of interest here to determine quantitatively the effect of finite chambrage on the mussle velocity of guns.
- 2. In reference (a) a qualitative description of what occurs during the firing of a conventional chambered gum is given in terms of the rarefactions and compression impulses which are present in the propellant gas. It is demonstrated that the propellant gas directly behind the projectile experiences chiefly the following tendencies for changes in pressure:
- a. A drop in pressure from the rarefactions of hold in the constant projectile
- \mathfrak{b}_* A rise in pressure from the compressions produced by the burning propellant
- c. A drop in pressure caused by the rarefactions reflected from the breach
- d. As a result of chambrage, a rise in pressure from the compressions reflected from the transition section, which joins the challer to the barrel.

A study will be made here of a gum with finite chambrage in which the propellant is initially all burned and which has a sufficiently long chamber so that the breach has no effect on the projectile motion. In this simplified gum the effects of the burning propellant and of the breach, (b) and (c) above, are absent; and the influence of chambrage on the accelerating projectile, (a) and (d) above, can therefore be obtained apart from these effects.

^{*} The propellant is assumed to burn only in the chamber.

3. The one-dimensional characteristic equations are applicable to the chamber (considered to be of constant diameter) and to the constant diameter barrel:

$$\frac{\partial}{\partial t}(u\pm\sigma) + (u\pm\alpha)\frac{\partial}{\partial x}(u\pm\sigma) = 0$$

In general, the solution of these equations requires a numerical stepby-step procedure for both the chamber and the barrel sections: this procedure can be applied to any length chamber and barrel. In the particular case analysed here of a long (effectively infinite length) chamber in which the propellant is initially all burned, the equation with positive signs of squation (1) integrates simply into

$$u + \sigma = \sigma_0 \tag{2}$$

for the chamber section; consequently, no step-by-step procedure is required in this case for the chamber section. (An effectively infinite length chamber is one sufficiently long so that no impulses or disturbances reflected from the chamber back end reach the projectile. See Section VI for a quantitative determination of this necessary length.)

4. The gas flow in the transition section, which joins the chamber to the bore, can be described by the two-dimensional unstandy adiabatic enargy equation and the two-dimensional unsteady continuity equation Since it is not feasible to use these equations, it is assumed that the rate at which the gas passes through the transition section is large relative to the rate at which conditions change within the trensition section. Then the equations which are applicable to rolate the conditions in a particular gas layer at the entrance of the transition section to those in this same gas layer when it is at the exit of the transition section are the steady equations of continuity and energy. By steady equations is meant that the equations

$$\varphi U A = constant$$
and $\frac{U^2}{2} + h = constant$ (4)

are applied to each gas layer, the constants in general being slightly different for each successive layer.

5. It can be shown by the same arguments as presented in reference (a) that the use of the steady flow equations to describe the gas flow between the chamber and the barrel of a gum yields a larger projectile velocity than the use of the unsteady equations. (The accuracy of the

See List of Symbols.

^{**} This is true because all downstream characteristic lines in the chamber originate from gas at rest and at the initial thermodynamic state of the gas. For a detailed explanation, see ref. ence (d).

steady flow approximation to the unsteady condition can be obtained from specific gun experimental results.*) In support of the use of this approximation, however, is the realization that the steady state condition is approached in the transition section of our simplified gun with the passage of time.

6. With the assumptions stated above and the additional assumption that the process is thermodynamically reversible, it is possible to study quantitatively the influence of chamber diameter on the muszle velocity of guns. The method of calculation and the results obtained are presented below.

II. Equations Describing the Behavior of the Propellant Gas and the Projectile

7. The gun is visualized as having a constant—diameter chamber of effectively infinite length joined by a transition section to a constant—diameter barrel. The projectile is positioned initially so that its back end is at the beginning of the uniform-area barrel section. It is assumed that the propellant burns completely before the projectile begins to move, producing the high-pressure propellant gas at initial and peak pressure po and sound velocity G_{\bullet} (see sketch 'welow).

The propellant gas is taken to be ideal with a ratio of specific heats, & , of 1.4. (The method used, however, can be applied to an imperfect gas of an ideal gas of any & (see reference (d).) The value of 1.4 is selected because experiments to confirm the theoretical conclusions obtained in this report were carried out using sir; those experiments are described in reference (b). For generality, directionless variables are used; these are listed below:

ect

10

J 01

$$\bar{x} = \frac{p_{\bullet} A x}{M[2/(8-1)]^2 \alpha_{\bullet}^2} = \frac{p_{\bullet} A x}{25 \alpha_{\bullet}^2 M}$$

$$\frac{1}{t} = \frac{p_{\bullet}At}{M[2/(8-1)]\alpha_{\bullet}} = \frac{p_{\bullet}At}{5\alpha_{\bullet}M}$$

[&]quot; Such experimental results are described in reference (b).

$$\overline{u} = \frac{u}{[2/(8-1)]a_o} = \frac{u}{5a_o}$$

$$\overline{a} = \frac{a}{[2/(\delta-1)]a_o} = \frac{a}{5a_o}$$

$$\overline{p} = \frac{p}{p_0}$$
, $\overline{p} = \frac{9}{p_0}$, $\overline{\sigma} = \frac{\sigma}{\sigma_0}$

8. It is assumed that each part of the propellant gas expands isentropically; therefore, since the propellant gas is ideal,

$$\overline{p} = \overline{p}^{8} = \overline{r}^{14}$$
, $\sigma = \int_{0}^{1} a \, dg/p = \frac{2\pi}{3} \frac{7(8-1)}{(8-1)}$
 $\overline{\sigma} = \frac{2\pi}{3} \frac{7(8-1)}{(8-1)} = 5\overline{a}$, $\overline{p} = \overline{\sigma}^{28/(8-1)} = \overline{\sigma}^{7}$

Parther, in the uniform chamber section and in the uniform barrel section the assumption is made that the gar motion is one derendinal in space. From this assumption and that of isentropicity, the unstandy one-dimensional momentum equation and continuity equation lead to the one-dimensional characteristic equations. Written in dimensionless form, these equations are

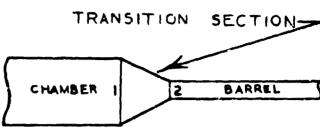

$$\frac{\partial}{\partial t}(\overline{u}\pm\overline{\sigma}) + (\overline{u}\pm\overline{a})\frac{\partial}{\partial \overline{x}}(\overline{u}\pm\overline{\sigma})=0$$

Equations (?) apply to both the chamber and barrel sections. Since the chamber is effectively infinite in length (and, consequently, the back part of the propellant gas remains at rest in its initial state in the chamber), the equation with positive signs of equation (?) becomes

Thus, for the chamber section the sum of the gas velocity, \overline{u} , and the Riemann function, $\overline{\sigma}$ (equal to 2/(x-1) times the sound velocity), remains a constant. This fact simplifies the treatment of the propellant gas in the chamber section. In the barrel section, however, no such simplification is possible; and equations (?) must be solved by a numerical ϵ -tep-by-step process.

9. In the transition section, which joins the chamber of cross-sectional area A₁ to the barrel of cross sectional area A₂, the gas flow is described by the steady flow equations of

flow is described by the steady flow equations of continuity and energy. With the subscript "l" denoting the state of the gas in the chamber at the entrance to the transition section, and the subscript "2" denoting the state of the gas in the tarrel at the exit of the transition section (see sketch), these equations are:

$$\rho_1 u_1 A_1 = \rho_2 u_2 A_2$$

and $h_1 + u_1^2 / 2 = h_2 + u_2^2 / 2$ (9)

In dimensionless form equations (9) become, with the use of equations (5) and (6),

$$(\overline{\alpha}_i)^{\frac{2}{k-1}} \overline{U}_{i_1} \frac{A_i}{A_2} = (\overline{\alpha}_k)^{\frac{2}{k-1}} \overline{U}_{k_1}$$
 (10)

and
$$\overline{U}_{1}^{2} + \frac{3-1}{2}\overline{\sigma}_{1}^{2} = \overline{U}_{2}^{2} + \frac{3-1}{2}\overline{\sigma}_{2}^{2}$$
 (11)

where the suthalpy h has been replaced by its equivalent for the ideal gar, (X -1) C /4.

10. Equation (8) can be applied in particular to the entrance of the transition section, yielding

$$\overline{U}_i + \overline{\sigma}_i = I \qquad (12)$$

With the assumption that the projectile is unopposed by air pressure in front and friction forces, the equation for the projectile acceleration is

$$\frac{d\overline{u}}{dt} = \overline{p}$$
 (13)

From equations (7), (10), (11), and (13) the entire behavior of the gas and projectile can be obtained for the chambered gun with effectively infinite length chamber.

- III. Obtaining Maximum Projectile Velocity for the Chambered Gum
- Il. By the use of the equations presented in Section II, the maximum projectile velocity can be obtained easily as a function of the ratio of chamber diameter to berrel diameter. The maximum projectile velocity is attained by an unopposed projectile in a gum of infinite barrel length. Although this velocity is an idealised limit, it is instructive to see the effect of chambrage on this limit.
- 12. As the projectile velocity increases in a chambered gun with infinite chamber length and infinite barrel length, steady state conditions in the transition section are approached, and the velocity at the exist of the transition section approaches the local sonic velocity. When the projectile has reached its maximum velocity, the steady state conditions will exist in the transition section, and the gas will be flowing with sonic speed. Thus, the steady flow equations (10) and (11) will exactly apply at this time; and, in addition, the velocity at the transition section exit can be equated to the sonic velocity without approximation.

$$(\overline{\sigma}_1)^{\frac{2}{k-1}}\overline{u}, \frac{A_1}{A_2} = (\overline{\sigma}_2)^{\frac{2}{k-1}}\overline{u}_2$$
 (10)

$$\overline{u}_{1}^{2} + \frac{x-1}{2}\overline{\sigma}^{2} = \overline{u}_{2}^{2} + \frac{x-1}{2}\overline{c}_{2}^{2}$$

$$\overline{u}_2 = \alpha_2 = \frac{y-1}{2} \overline{o}_2 \tag{14}$$

where all the quantities are for the time when the projectic velocity is a maximum.

1)

oal

ı in

13)

13. As the chamber is effectively infinite in length, equation (8) can be applied to the gas in the chamber at the entrance to the transition section at this time

$$\overline{\mathbf{u}}_{1} + \overline{\mathbf{o}}_{1} = 1 \tag{12}$$

To determine the maximum projectile velocity, the impulses traveling downstream from the transition section toward the projectile may be examined. For each of these impulses the quantity $\widetilde{q}_{L}+\widetilde{G}$ is a constant (by equation (7)), a different constant for each impulse, equal to $U_{Q}+\widetilde{G}_{Z}$, since they travel from the exit of the transition section. When the projectile is traveling at maximum speed, the pressure of the gas directly behind it is zero, and beauer the Riemann function \widetilde{G}_{L}

^{*} The maximum velocity with which gas can issue from the chamber into the barrel is the local velocity of sound; this is true whether the flow is steady or unsteady.

this gas (by equation (6)) is zero. Therefore,

$$\overline{u}_{M} = (\overline{u} + \overline{\sigma})_{AT PROJ.} = \overline{u}_{2} + \overline{\sigma}_{2}$$
 (15)

where U. is the dimensionless maximum projectile velocity, and the quantities in the equation refer to the time when the projectile velocity is a maximum. With equation (14) the maximum projectile velocity becomes

$$\overline{u}_{M} = \frac{3+1}{5-1}\overline{\alpha}_{2} = \frac{3+1}{2}\overline{\sigma}_{2} \qquad (16)$$

14. From equations (10), (11), (12), (14), and (16) the relation between the maximum projectile velocity and the ratio of the chamber-to-bore cross-sectional area (or chamber-to-bore diameter) car he obtained for the infinite-chamber-length gum. $A_1/A_2 = (D_1/D_2)^2$

$$= \left[\frac{\overline{u}_{M}}{1 + \sqrt{\left(\frac{X-1}{2}\right)(\overline{u}_{M}^{2}-1)}}\right]^{\frac{2}{X-1}} \left[\frac{\overline{u}_{M}}{1 - \frac{2}{X-1}\sqrt{\left(\frac{X-1}{2}\right)(\overline{u}_{M}^{2}-1)}}\right]^{(17)}$$

It is evident from equation (17) that, as expected, the maximum projectile velocity for an infinite-chamber-length, constant-diameter gun $(D_1/D_2=1)$ is $2 C_0/(8-1)$ (i.e., U_{-1} is equal to 1). Further, it is seen that as D_1/D_2 approximate an infinite value — this would be the case of the optimum chambrage gun — (U_{-1}) approximate the value $(\sqrt{8+1}/2)$ (or U_{-1} approximates $(\sqrt{8+1}/2)$ $C_0/(8-1)$); this result U_{-1} with this maximum velocity result obtained in reference (a) for the optimum observes gun.

- 15. For a propolisht gas of 8 equal to 1.4, the maximum projectile velocity has been evaluated as a function of D_1/D_2 from equation (17). The result is shown in Figure 1.
- 16. The increase in the maximum projectile velocity as a result of chambrage divided by the increase in the projectile velocity as a result of optimum chambrage, expressed as a percentage, is designated the percent of the optimum chambrage maximum velocity increase. Thus, percent of the optimum chambrage maximum velocity increase.

$$= \frac{u_{M} - 2\alpha_{o}/(8-1)}{(\sqrt{2/(8+1)}) 2\alpha_{o}/(8-1) - 2\alpha_{o}/(8-1)}$$
(18)

- <u>un - 1</u>

This percentage has been calculated as a function of chamber-to-bore dismeter (D_1/D_2) for both a ξ equal to 1.4 propellant gas and a ξ equal to 1.25 propellant gas. The results are presented in Figure 2 as a single curve, because, quits sur, risingly, the percentage was

CONFILMITIAL

found to be almost exactly the same for each & this demonstrated that the percentage of the optimum chambrage maximum velocity increase is practically independent of & between the limits of & equal to 1.25 to 1.4.

?7. It might be reiterated at this point that the equations used in obtaining figures 1 and 2 are not approximate ones but exactly describe the assumed isentropic gas flow for an infinite-chamber-length gun when the projectile velocity is a maximum.

IV. Nother of Calculation of the Projectile Value ty for a Chambered Gun

- 18. To calculate the projectile velocity for a chambered gum of effectively infinite length from equations (7), (10), (11), and (13), it is necessary to use in the barrel section the step-by-step numerical characteristics method. (This method is outlined in references (b), (c) and (f), and in many other reports.) This requires the use of a characteristics net (two sets of intersecting characteristic lines in the x-t plane -- one with slope U+U, along which U+V is constant, another with slope U-U, along which U-V is constant). The characteristic lines forming the set can be interpreted as the path of disturbance angulass, since, as one goes along a characteristic line, one travels at the same speed as a disturbance would, that is, at the loos) velocity of sound relative to the months, E(X).
- 20. A schematic dimining of a characteristics diagram for a chambered yun is shown in Figure 3. In this figure the points 0, A, B, C, D, etc. are points on the projectile path; the line 0-0' represents the heginning of the constant-diameter barrel section, the line ".T' represents the end of the constant-diameter chamber exciton.
- 20. For the calculation the relationship between conditions at the entrance and exit to the transition section is obtained from equations (10), (11), and (12). Thus, these equations can ω combined to yield the relation between \overline{G}_i and \overline{G}_2 ,

$$\frac{1}{\overline{\sigma_i}} = \left[+ \left\{ \frac{1 - (\overline{\sigma_i}/\overline{\sigma_i})^2}{\left[\left[\frac{2}{3} - 1 \right] \right] \left[(\overline{\sigma_i}/\overline{\sigma_i})^4 / (\frac{1}{3} - 1) \right]} \right\}^{\frac{1}{2}} (19)$$

With equation (19), equations (10) and (12) conveniently yield the relations between \overline{G}_1 , \overline{G}_2 , \overline{U}_1 and \overline{U}_2 for use in the calculation.

21. To begin the numerical solution, as initial point along the projectile path (point A in Figure 3) can be obtained by assuming that the pressure-velocity relationship behind the projectile up to that point

8 COMPIDENTIAL

is the same as that at the exit of the transition section. This approximation has been found to be satisfactor; up to $U_* = .08$ for the optimum chambrage gum; it can be made as accurate as desired by taking point A as close as desired to point 0.

22. The characteristics not is continued from point A by the usual numerical methods. Thus, from points 0 and A, point 1 is calculated; from 1 and A, point B is calculated, and so on. Conditions at the smit of the transition section (represented by points 1, 2, 3, 4, etc.) are calculated from the value of U.—F on the upstream impulses (e.g., A-1, B-2, C-3, etc.) and the use of equations (19), (10), and (12). To prevent the characteristics net from becoming too coarse, a parabola is fitted through the points D, E, and F in Figure 3. With this calculated the points α , β , γ , ϵ , and ϵ are calculated and used to continue the characteristics net.

V. Calculated Projectile Behavior for a Gun with Chamber-to-Bore Diameter Ratio Equal to 1.5

23. From the relation between the maximum velocity and the chamber-to-bore diameter ratio, equation (17), and the expression for the percent velocity increase, equation (18), the diameter ratio which yields a value of 50% of the optimum chambrage maximum velocity increase can be calculated. This diameter ratio [27] to equal to 1.511 for a % equal to 1.4 propollant gas (and approximately equal to 1.511 for a % a % equal to 1.25 gas (see Figure 2)); therefore, the calculation of projectile tehavior was done for a chambered gum with D1/D2 equal to 1.511. A portion of the actual characteristics diagram is shown in Figure 4. The calculated values for points along the projectile path of the D1/D2 = 1.511 gum are given in Table 1 (1.511 is often denoted 1.5).

24. Plots of projectile velocity \overline{u} versus travel \overline{x} are given in Figure 5 for guns using a $\overline{u} = 1.4$ gas, with chamber—to—bore diameter equal to 1 (see reference (a)), 1.511 (the case calculated here), and so (optimum chambrage gum). (Figure 6 is the \overline{u} versus \overline{x} plot in the lower velocity region.) It is apparent from these curves that the velocity of the $D_1/D_2 = 1.511$ gun is approximately halfway between the $D_1/D_2 = 1$ and the $D_1/D_2 = \infty$ gun velocities. Thus, the $D_1/D_2 = 1.5$ gun, which yields 50% of the optimum chambrage velocity increase at maximum velocity, is seen to yield approximately 50% of the optimum chambrage velocity increase for all velocities. The curve of Figure 2, which applies to the maximum velocity increase at infinite travel; which applies to the maximum velocity increase of a chambered gun therefore, can be applied to the velocity increase of a chambered gun at any projectile travel. This curve is replotted in Figure 7 with the ordinate labeled the "percent of the optimum chambrage velocity increase",

$$\frac{U_{D_1/D_2} = 1}{U_{D_1/D_2} = -U_{D_1/D_2} = 1}$$

$$CONFILMTIAL$$

where u is the projectile velocity of the chambered gum, $U_{D_1/D_2} = 1$ is the projectile velocity of the constant-diameter gum, and $U_{D_1/D_2} = \infty$ is the projectile velocity of the optimum chambrage gum, all to be taken at a given projectile travel. Figure 8 is a U versus X plot for chambered gums $(D_1/D_2 = 1, 1.5, \infty)$ drawn for 8 equal to 1.25 by analogy with the 8 equal to 1.4 plots.*

25. Figures 5, 5 (or 8), and 7 can now be employed to obtain the projectile velocity for any chambered gun with effectively infinite length chamber. For example, to obtain the muzzle velocity of an effectively infinite chamber length gun of $D_1/D_2 = 2$, and $\chi = 1.4$, whose dimensionless bardel length $\bar{\chi}$ equals .015, one would find from Figure 7 that the optimum chamicage velocity increase is 70 percent. From Figure 6, $\bar{\chi}_{0,|D_{2}|}$.126, $\bar{\chi}_{0,|D_{2}|}$.149; therefore

$$\frac{\bar{u} - .126}{.149 - .126} = .70$$

and the velocity of this gun would be

$$\bar{u} = .142$$
, or $u = .71$ a.

"I. Coloulation of the First Impulse Reflected from the Breach

26. It has been empiresised that the analysis presented in this paper is for a gam whose unamber length is effectively infinite. For a gam in which the propellant is initially all purned and motionions, it projectile behavior is unaffected by the chamber back end (the broach) until the rerefeation impulses which originate from the projectile motion are reflected from the breech and resub the projectile. (The first such impulse is referred to as the first reflected impulse from the hearth.) A gun whose chamber length is effectively infinite is, therefore, one in which the chamber is of sufficient length so that the first reflected impulse does not leach the projectile while it is in the barrel. A gum whose barrel langth is short would require a relatively short chamber for an effectively infinite chamber length, whereas a long barreled gun would require a relatively . ng chamber. The impaires reflected from the breech which originated from the projectile are rerefaction (mouleses) when they reach the projectile, they lover the pressure of the gazbehind the projectile, and, consequently, the projectile velocity is less than if there were no breech reflecting those impulses. As the chamber-to-tore diameter ratio increases, the effects of these reflected

COMPIDENTIAL

[&]quot;An error in the δ = 1.25 case occurring in reference. (a) has been corrected in Figure 8.

rerefaction impulses become less and less (see discussion in reference (a)). In fact, the one-dimensional theory used here demonstrates that if D_1/D_2 is infinite, there is no effect due to a breech.)

27. Obtaining the chamber length necessary to be effectively infinite requires the calculation of the path of the first reflected impulses. As before, the cases of $D_1/D_2=1$, 1.5, and so are considered. For a gum of constant diameter, Heybey (reference (e)) has obtained analytic expressions for the path of the first reflected impulse in the case of a perfect gas. These may be transformed to yield

$$\overline{X}_{oe} = \frac{(8-1)^2}{2(o+1)} \left[\frac{1}{(1-\bar{u}_{ist})^{(8+1)/2(8-1)}} - 1 \right]$$
(20)

where x_{00} is the dimensionless distance from the breech to the initial position of the projectile back and and U_{igt} is the dimensionless projectile velocity when the first reflected impulse reaches the projectile. The relation between the projectile velocity u and the travel x for a constant-diameter gun (reference (e)) is

 $\overline{X} = \frac{(8-1)^2}{2(8+1)} \left[\frac{2 - (8+1)(1-\overline{u})}{(8-1)(1-\overline{u})^{(8+1)/(8-1)}} + 1 \right]_{(21)}$

From equations (20) and (%) the half-scar, chamber lengths. Xoo, to be effectively infinite can be obtained as runctions of projective (i.e. barrel length) and projectile velocity. These relations are shown in Figures 9 and 10 as the D₁/D₂ = 1 plots.

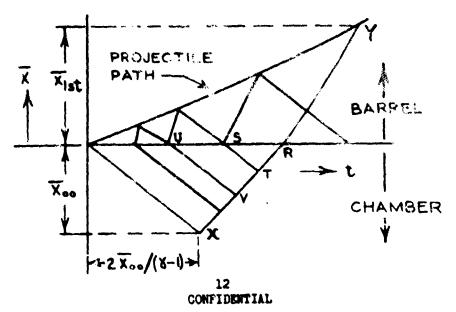

28. For simplicity in calculating the path of the first reflected impulse in the case of the chambered gume, the length of the constitute section between the chamber and barrel is taken to be zero. An examination of equation (10) or (19) demonstrates that, for the optimum chambrage gum $(D_1/D_2=CO)$, the valocity of the gas in the chamber section is zero, and the pressure, sound valocity, and other gas conditions in the chamber remain constant at their initial values. Thus, the impulses in the chamber section travel at the initial sound velocity; the time required for the first impulse to travel from the transition point and back is equal to $2 \times_{CO} / C_O$ or, dimensionlessly, $4 \times_{CO} / (8-1)$.

29. Eac: value of time (e.g., P in the sketch below) along the $\overline{X}=0$ line (the beginning of the barrel) obtained from the optimum chambrage calculation can be taken to correspond to the time required for the first impulse to reflect from the breach to the transition section; the breach distance \overline{X}_{00} is equal to (X-1)/4 of this time, and the velocity, \overline{U}_{igt} , and position, \overline{X}_{igt} , of the projectile when the first impulse reaches it at Q can be obtained from the optimum chambrage calculation by following the downstream impulse from P. In this manner the paths of the first reflected impulses for the $D_1/D_2=00$ case are

obtained. The resultant $D_1/D_2 = \infty$ plots are shown in Figures 9 and 10.

30. For the $D_1/D_2=1.5$ case the characteristic equations can be appeared in the chamber section (where $U+\overline{D}=1$) to obtain the path of the first reflected impulse. From points R and S used previously in the $D_1/D_2=1.5$ calculation, on the X=0 line (see sketch below) point T can be calculated; from T and U the point V can be calculated; etc.

Point X, which specifies \overline{X}_{ee} , is the intersection of the downstream characteristic R - T - V... and the first upstream impulse (of slope -2/(X-1)). Since point Y on the projectile path has been calculated previously, the first reflected impulse path is completely known. In this manner the chamber length to be effectively infinite was calculated for the $D_1/D_2 = 1.5$ case; the results are shown in Figures 9 and 10.

31. The curves of Figures 9 and 10 illustrate that the $D_1/D_2=1.5$ case is approximately midway between the $D_1/D_2=1$ and $D_1/D_2=00$ cases; therefore, the plot of Figure 2 (or 7) can be used to obtain the chamber lengths necessary to be effectively infinite for diameter ratios other than 1, 1.5, $-\tau$ co.

VII. CONCLUDING REMARKS

- 32. It is seen that the quantitative results obtained here are in agreement with the qualitative description of the effect of chambrage given in reference (a). There are mbrage and a burning propellant are pictured as creating compression impulses which increase the projectile velocity. Alternately, chambrage and a burning propellant can be viewed as making possible the closer positioning of the propelling gas to the projectile, thereby increasing the projectile velocity.
- 3). It is to be emphasised that the conclusions of which is this property on the influence of chambrage are applicable under the conditions that (a) the anamber and bearel are cylindrical, (b) the propellant gas is all burned before the projectile moves, (c) the propellant gas is an Meal sas, (d) the expansion of the gas is isomtropic, (e) the chamber is sufficiently long that the breeds has no effect on the projectile motion, and (f) the steady flow equations apply in the transition section. The validity of the last condition must await experimental results. The other conditions are not satisfied by conventional guar, and caution must be exercised in the application of those results to such guns; however, they are closely approached in some unorthodox guns to which these results can be directly applied. For conventional guns (i.e., in which the pubpellant burns during the projectile motion) the velocity gain from chambrage can be less than calculated here. This is due to the fact that a pressure sustaining effect behind the projectile can be achieved from the propellant's occlinued burning. This pressure sustaining effect from continued burning is more and more difficult to obtain as projectile velocities ero increased (because of the high rates of burning required), but a pressure sustaining effect from chambrage is obtainable at high valuaties. Thus, the use of chambrage is particularly advantageous in high-vericity conventicual guns. NAVORD Report 3717 (in preparation) gives an approximate waterd of treating chambrage in conventional gun celculations.

LIST OF SYMBOLS

CL - Velocity of sound

A, - Cross-sectional area of propellant chamber

Az - Cross-sectional area of barrel bore

Di - Diameter of propellant chamber

Dg - plameter of barrel bore

h - Enthalpy

M - Mass of projectile

D - Pressure

t - Time

U - Cas or projectile velocity

X - Position coordinate of gas element

 $E_{\phi\phi}$ - Distance from breach to transition section

Specific heat ratio

P - Gas density

 σ - Riemann function, defined as $\int (cL d\rho/\rho)_S$, S = entropy

A symbol with a bar is dimensionless and is related to the dimensional quantities by equations (5). The subscript "o" refers to the initial state of the gas at rest in the chamber; the subscript "1" denotes the state of the gas in the chamber at the entrance to the transition section, and the subscript "2" denotes the state of the gas in the barrel at the exit of the transition section.
